Objectives

With the popularity of computers, the frequency of the appeals to the neck, shoulder, and musculoskeletal abnormalities has been increased in students and professionals who frequently use the computers. The anterior head posture (turtle neck syndrome), which frequently occurs in long-term computer working group, is a cause of diverse musculoskeletal, nerve and vascular disorders because the head moves in front of the gravitational center line and becomes chronic. It is difficult for the general people to know whether the intervention methods so far are a correct cervical posterior motion of the cervical deep muscle. Analogue methods are mostly used, and there are digital devices only for the prevention of the head posture. So we decided to develop a digitized head anterior rehabilitation tool.

Methods

When the subject is placed in a lying position and presses the pillow after the posterior cervical spine, the target receives inputs of position, value and degree of bending through Arduino Bluetooth module via FSR•FLEX sensors. After receiving the above information, the application executes the conditional statement operation (exercise method), and the vibration is output when the event processing is completed (Fig. 1). In the right posture, the patient puts pressure on the pointing part to take necessary positions for rehabilitation treatment. The patients will output vibration or sound when the internal event processing is completed within the app. Then, they enter the position, value of the pressure point and the degree of bending, and send sensor value to Bluetooth. The specialist identifies the progress of the treatment by sending a graph of data. They perform the conditional operation according to sensor value in application.

Results

If the patients apply this posterior cervical spine tool to a person with a anterior head posture as a steady exercise, the neck adjustment is returned to the normal range and the symptoms of the anterior head posture and musculoskeletal symptoms will be alleviated considerably. Conclusions: We suggested it is meaningful that this is designed to induce the correct operation and make it easier to use than the existing equipment for Turtle neck syndrome. In addition, if the exercise information is used in the medical field, it will be more helpful to understand patient's physical condition. Keywords: Forward head position (FHP), Turtle neck syndrome, Rehabilitation exercise, FSR•FLEX sensor.
